## **Abstract.**

Biodiesel, an alternative diesel fuel consisting of the alkyl monoesters of fatty acids from vegetable oils and animal fats, can be used in existing diesel engines without modifications. However, property changes associated with the differences in chemical structure between biodiesel and petroleum-based diesel fuel may change the engine's injection timing. These injection timing changes can cause different exhaust emissions and performance than the optimized settings chosen by the engine manufacturer. The properties that will have the greatest effect on the fuel injection timing are the speed of sound, the isentropic bulk modulus, and the viscosity. The objective of this study was to measure the isentropic bulk modulus and speed of sound of biodiesel and the pure esters that are the constituents of biodiesel at temperatures from 20°C to 100°C and at pressures from atmospheric to 34.5 MPa. Future work to identify the effect of viscosity is anticipated. The measured values of density, speed of sound, and isentropic bulk modulus are shown and correlations showing the dependence of pressure at each temperature are provided. A simple analysis using measured values of biodiesel and diesel fuel properties indicates that property changes could cause approximately 1° of injection timing advance. Since NO<sub>x</sub> emissions increase with advanced timing, this effect may be partially responsible for the increase in NO<sub>x</sub> sometimes observed in the exhaust of biodiesel fueled engines.

## **1. Introduction**

Biodiesel, an alternative to diesel fuel consisting of the alkyl monoesters of fatty acids from vegetable oils and animal fats, can be used in existing diesel engines without modifications. However, property changes associated with the differences in chemical structure between biodiesel and petroleum-based diesel fuel may change the engine's injection timing. These injection timing changes can cause different exhaust emissions and performance than the optimized settings chosen by the engine manufacturer. The properties that will have the greatest effect on the fuel injection timing are the speed of sound, the isentropic bulk modulus, and the viscosity.

Figure 1 shows recently obtained data for the fuel injection line pressure from an engine being used for an unrelated project [1]. The two fuels designated HPVB and LPVB are soybean-based biodiesels. Data is shown for the two biodiesel fuels, 20% blends of the fuels in No. 2 diesel fuel, and the No. 2 diesel fuel itself. These data show that for fixed injection pump timing, the injection pressure pulse for the biodiesel was  $1.5^\circ - 2.0^\circ$  advanced from the diesel fuel baseline. The injection timing advance is probably due to differences in the fuel properties such as the bulk modulus and speed of sound. The higher viscosity of the biodiesel may also have an effect. Since NO<sub>x</sub> emissions increase with advanced timing, this effect may be partially responsible for the increase in NO<sub>x</sub> observed with biodiesel. The engine used for this testing was a John Deere 4276T, 4 cylinder, diesel engine equipped with a distributor-type injection pump.

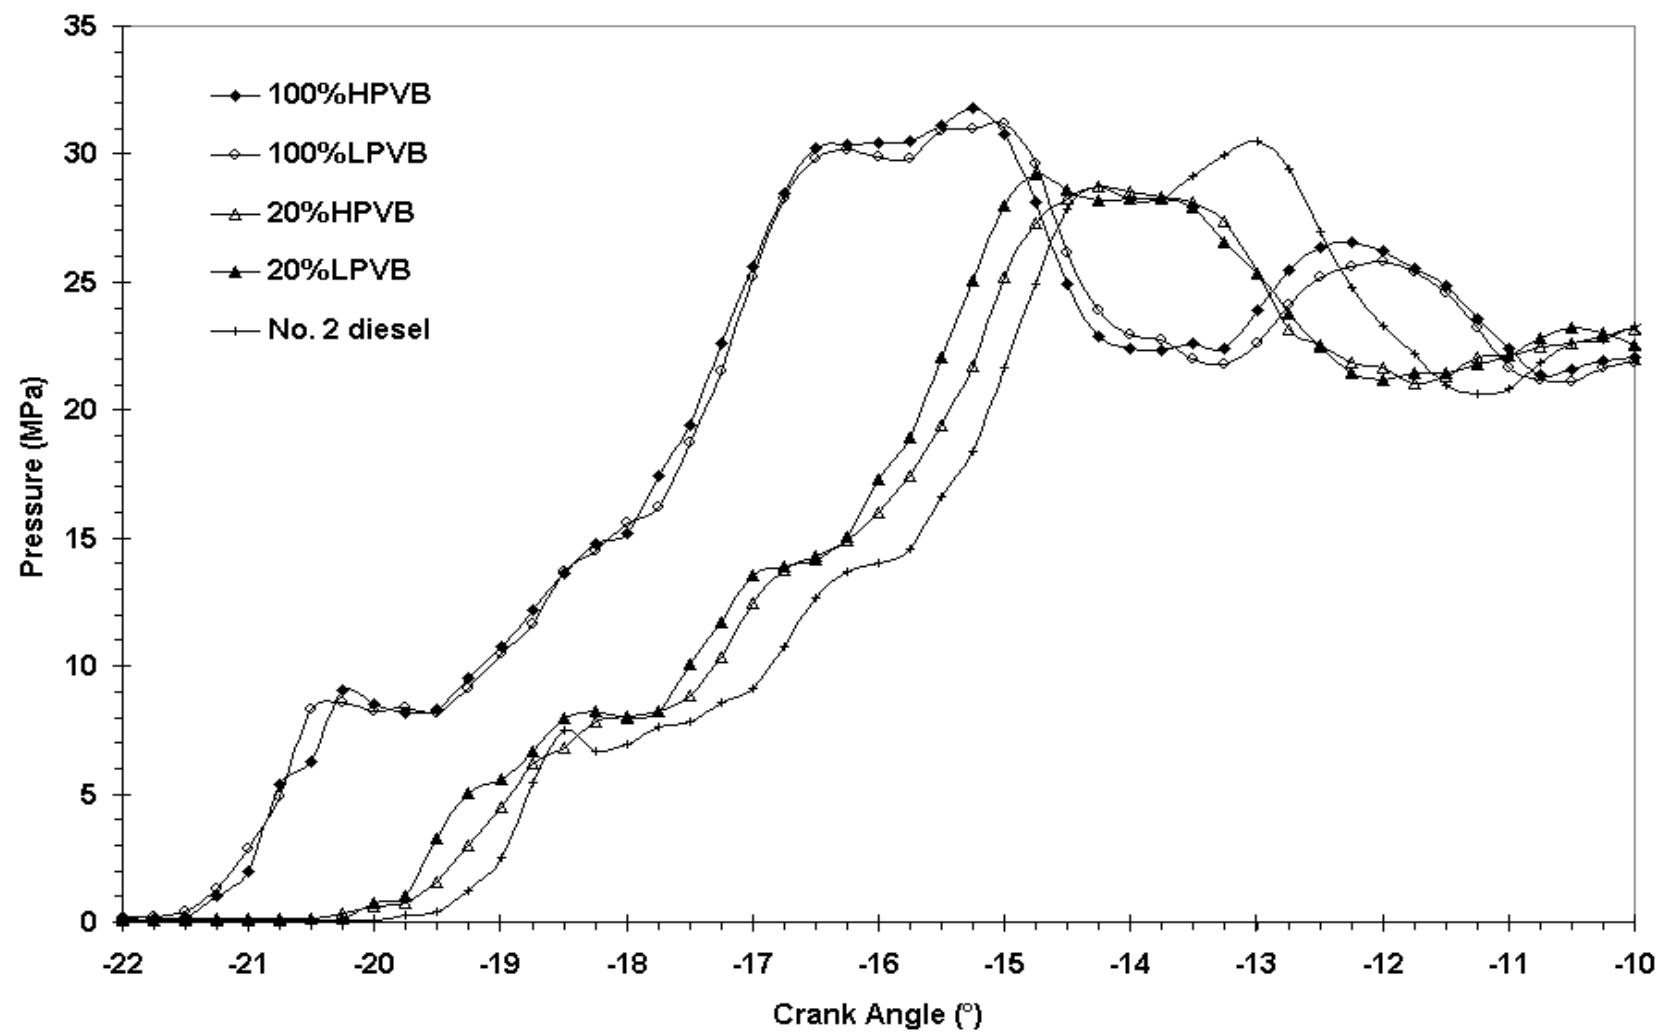

Figure 1. Injection line pressure for biodiesel and No. 2 diesel fuel.

The objective of the current project was to measure the isentropic bulk modulus and speed of sound of biodiesel at temperatures from 20°C to 100°C and at pressures from atmospheric to 5,000 psi. These ranges should cover many of the commonly encountered injection timing characteristics since many engines have nozzle opening pressures below 5,000 psi. In addition to measuring the properties of biodiesel made from soybean oil, we will be measuring the properties of the pure ester constituents of biodiesel.

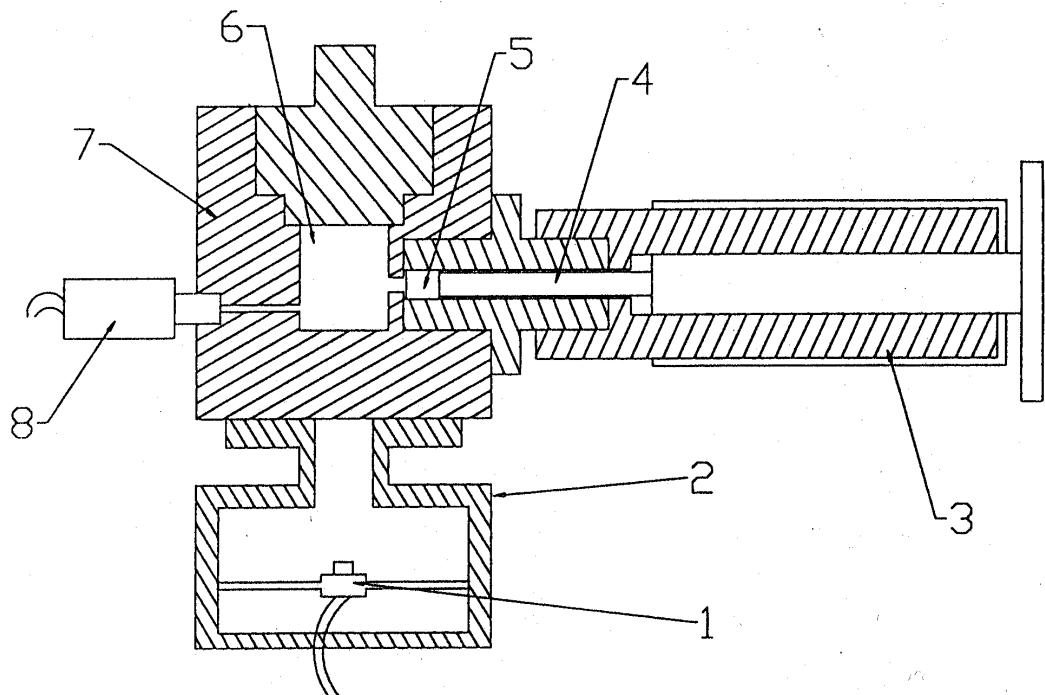

This report presents the results of measurements of these properties for 21 pure esters and ester blends. These compounds are listed in Table 1. Samples of the compounds shown in Table 1 were provided by Michael Graboski, Robert McCormick, and Teresa Alleman of the Colorado Institute for Fuels and High-Altitude Engine Research at the Colorado School of Mines. Tables B-1 through B-4 in Appendix B provide chemical analyses and property data for the different esters that were tested.

## **2. Equipment and procedure**

The ultrasonic pulse echo technique was used to measure the speed of sound in the esters from 20°C to 100°C and from atmospheric pressure to 34.5 MPa [2-6]. A pressure vessel with a piston and cylinder assembly for raising the pressure was fabricated and an ultrasonic transducer was located at the bottom of the vessel as shown in Figure 2. A Panametrics Model 5072 PR general purpose ultrasonic pulser/receiver and a Panametrics 10 MHz videoscan immersion transducer (Waltham, MA) were used.

Table 1. Fuel Samples

Methyl Laurate	Methyl Linoleate	Methyl Lard
Methyl Palmitate	Methyl Linolenate	Methyl Canola
Methyl Stearate	Methyl Oxidized Soy	Methyl Soy Gold
Methyl Oleate	Methyl Tallow	Methyl Yellow Grease

Figure 2. Cross section of the Pressure Vessel.

Signals were captured with a Hewlett Packard Model 54601A 100 MHz, 4 channel digital oscilloscope (Colorado Springs, CO). System pressure was measured using a Sensotec Model 2 Z/1108-04Z9 pressure transducer (Columbus, OH). To obtain elevated temperatures the entire pressure vessel was submerged in a temperature controlled bath.

The speed of sound was determined by measuring the time difference between the ultrasound echo reflected back to the transducer from the interface where the signal passed from the pressure vessel into the sample fluid, called the first echo and from the reflection when the signal left the sample and reentered the vessel wall, called the second echo. A diagram showing the echoes is given in Figure 3. The distance traveled by the sound wave during this time period, which is two times the sample thickness, was divided by the elapsed time to give the speed of sound in the fluid.

The first echo was a stationary echo with a fixed time delay from the zero trigger event. It was identified using calculations based on the speed of sound in water and stainless steel. The second echo was found from observation and was the only echo that moved with pressure fluctuations in the cell. After finding the second echo, the elapsed time was recorded starting with the atmospheric pressure level. Then, the pressure level in the cell was raised to 5,000 psi and lowered to atmospheric pressure in 1,000 psi steps.

Density measurements were taken simultaneously with the speed of sound measurements by using a vernier to show the piston location in the cylinder. To determine the density of the sample at elevated pressures, the sample density was initially measured at atmospheric pressure using a specific gravity balance. As the sample pressure was raised using the piston and cylinder, the piston position was used to calculate the volume change. Since the sample mass was constant, the volume change was used to determine the density change. The density change could be combined with the initial density measurement, to give the density at the elevated pressure. For each temperature increment a known amount of sample was discharged starting at 20°C and the density was calculated from the volume change at the higher temperature level. A correction was calculated for the expansion of the vessel at high pressure and high temperature, although this was small for all of the data presented here.

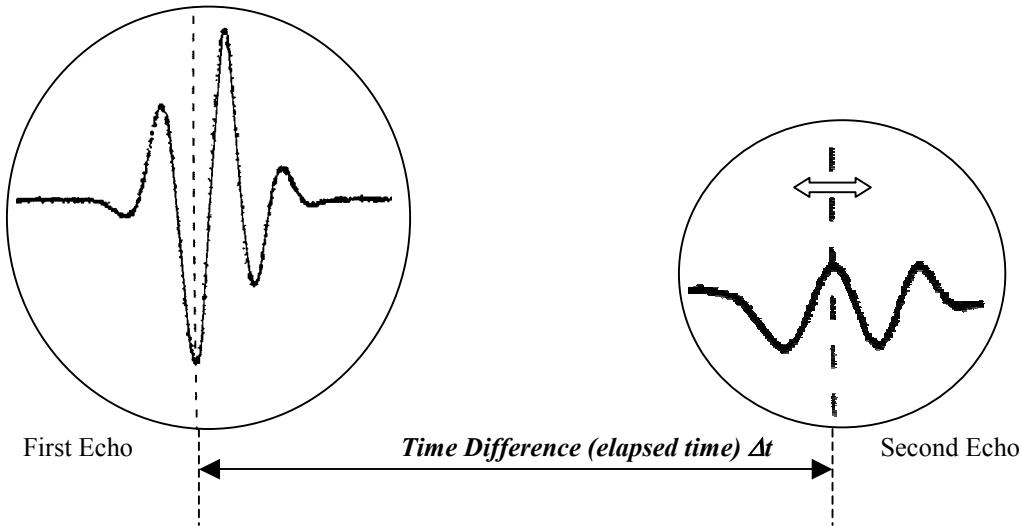

Figure 3. Ultrasonic Signals

Figure 4 shows the complete experimental setup. The screw adjustment for raising the sample pressure is visible extending from the right side of the stainless steel pressure vessel. The metal housing on top of the pressure vessel contains the ultrasonic transducer and provides the cooling the transducer needs to stay below 50°C. Figure 4 shows an end view of this housing looking into the transducer. The adjustable supports for the transducer are visible in this view. They allow the transducer to be aligned for maximum signal strength.

Figure 4. Experimental apparatus for ultrasound measurements.

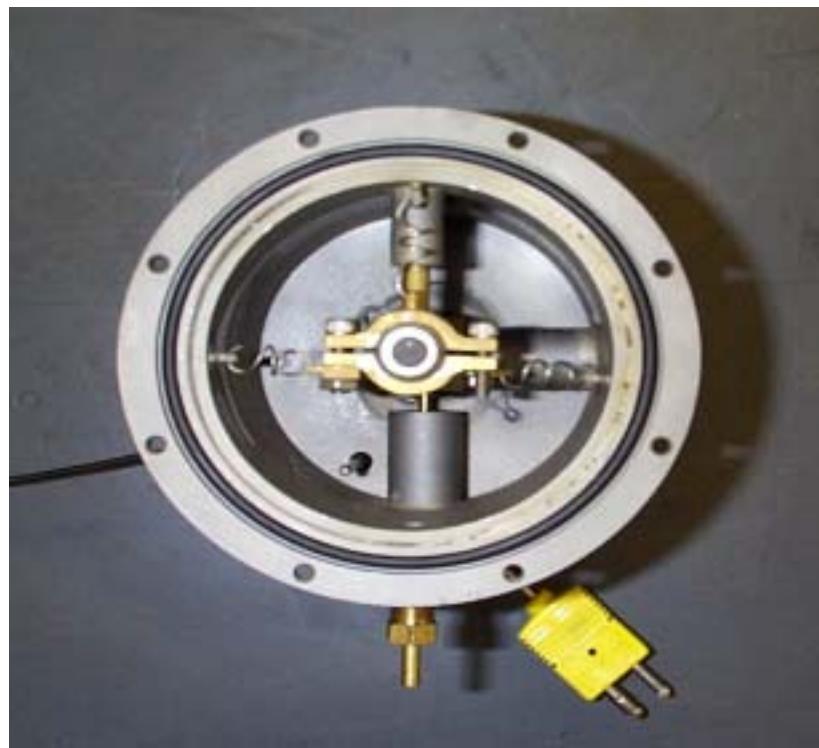

Figure 5. End view of ultrasonic transducer showing alignment screws.

The isentropic bulk modulus was calculated from the measured density and speed of sound using the following equation [5, 7].

$$\beta = c^2 \times \rho \quad (1)$$

where  $\beta$  is the isentropic bulk modulus,  $c$  is the speed of sound in the sample, and  $\rho$  is the density.

The two primary concerns with the use of the pressure vessel technique for density measurement were ensuring that air bubbles were eliminated from inside the vessel and that no fluid leaked from the vessel during the test. If air bubbles were present, their presence was expected to cause variations in measurements as the pressure vessel was filled, emptied, and refilled again. Thus, the pressure vessel was filled with the sample fluid two times and each time two sets of data were collected as the pressure was varied. Half of the measurements were collected while increasing the pressure and half while decreasing the pressure. This was to identify leakage from the chamber or any other hysteresis effects. Thus, a total of four data points were collected for each pressure and temperature level. Subsequent analysis showed no statistically significant difference between the measurements associated with different filling operations or with measurements taken while increasing or decreasing the pressure. Therefore, all 4 measurements were averaged and included in the confidence limit calculations. All measurements were taken from 20°C to 100°C except for methyl palmitate, methyl stearate, 2:1 methyl stearate methyl linseed, methyl hydrogenated soy, ethyl hydrogenated soy, ethyl stearate, and n-octadecane which were solid at 20°C. The lowest temperature at which measurements were taken for these esters was 40°C.

### **3. Results**

The density, speed of sound and isentropic bulk modulus of the fuel samples showed linear relationships at fixed temperature as the pressure was varied. The linear regression coefficients at the five temperatures for each fuel are provided in Tables A-1 through A-23 in Appendix A. The actual raw data on which the correlations are based is provided in Appendix C. The following discussion focuses on identifying common trends as the esters with different levels of saturation or chain length are compared.

Figures 6, 7, and 8 show the effect of temperature on the density, speed of sound, and isentropic bulk modulus for fuels with different levels of saturation. All three properties tend to increase as the degree of unsaturation increases.

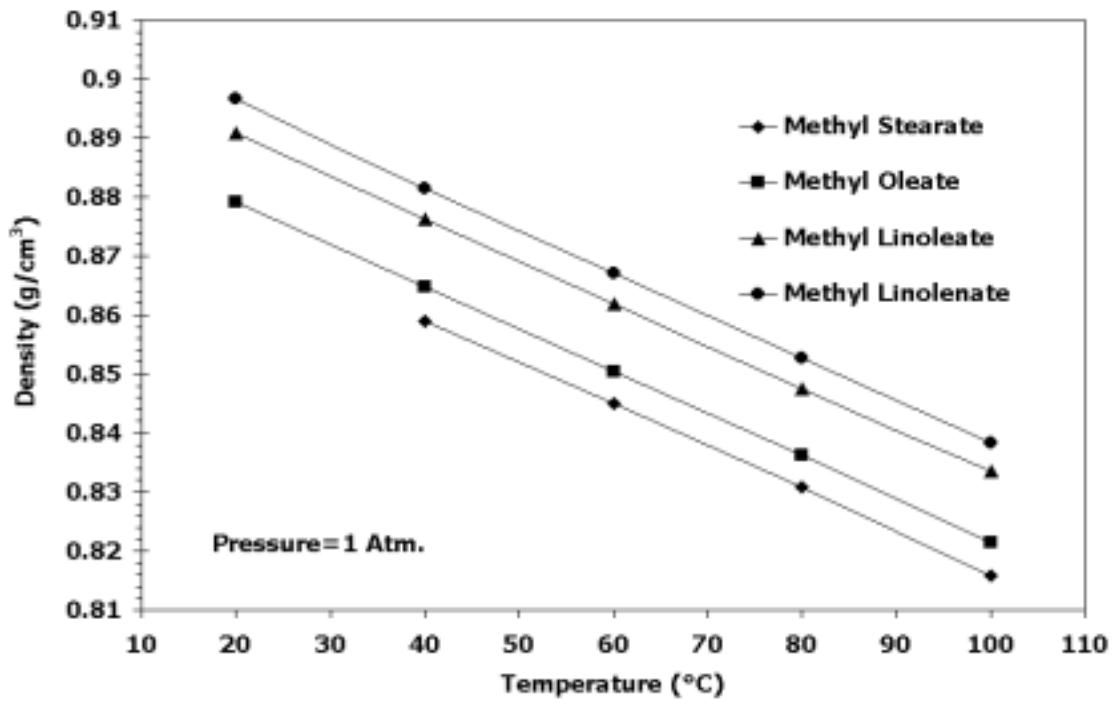

Figure 6. Temperature dependent saturation effect on density at atmospheric pressure.

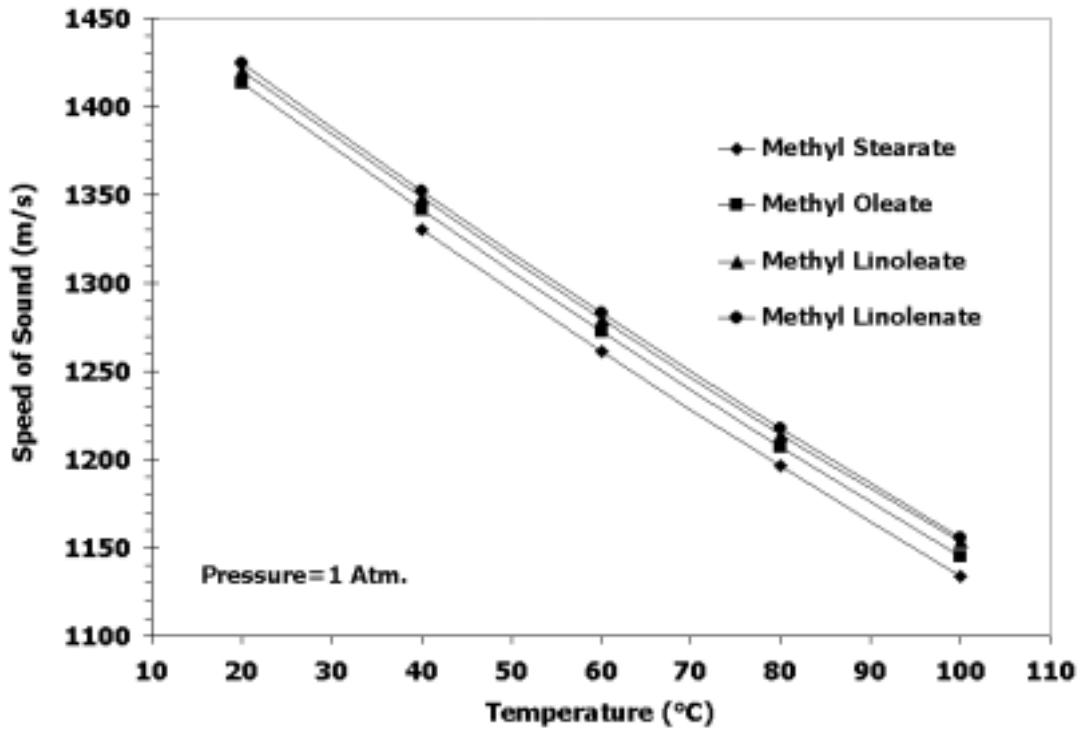

Figure 7. Temperature dependent saturation effect on speed of sound at atmospheric pressure.

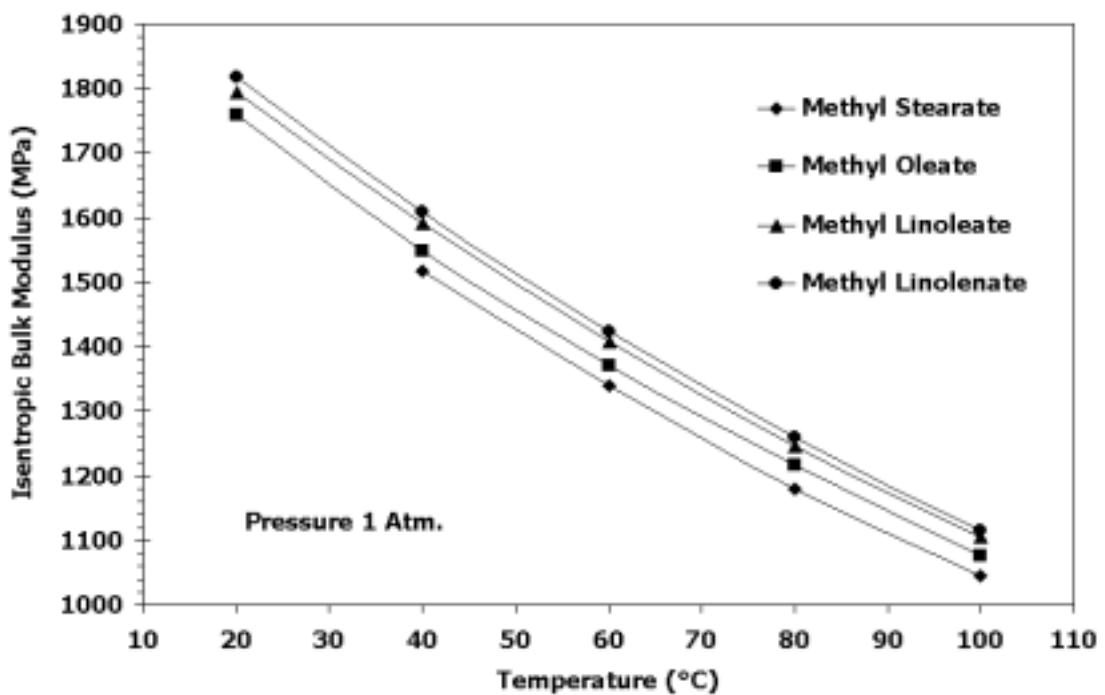

Figure 8. Temperature dependent saturation effect on isentropic bulk modulus at atmospheric pressure.

Methyl stearate has the lowest density, speed of sound, and isentropic bulk modulus and methyl linolenate has the highest. All of the compounds appear to have approximately the same property variation with temperature as indicated by similar slopes of lines on these figures.

The variations in the three properties as the pressure increases are shown in Figures 9, 10, and 11 for the four levels of saturation. The temperature for these data was 40°C. A complete comparison could not be made at 20°C because methyl stearate is a solid at this temperature. Again, the density, speed of sound, and isentropic bulk modulus are higher for the more unsaturated esters. Figures 6 through 11 indicate that the increase in properties is not uniform as each double bond is added. The change in density from oleate to linoleate is much greater than from stearate to oleate or linoleate to linolenate.

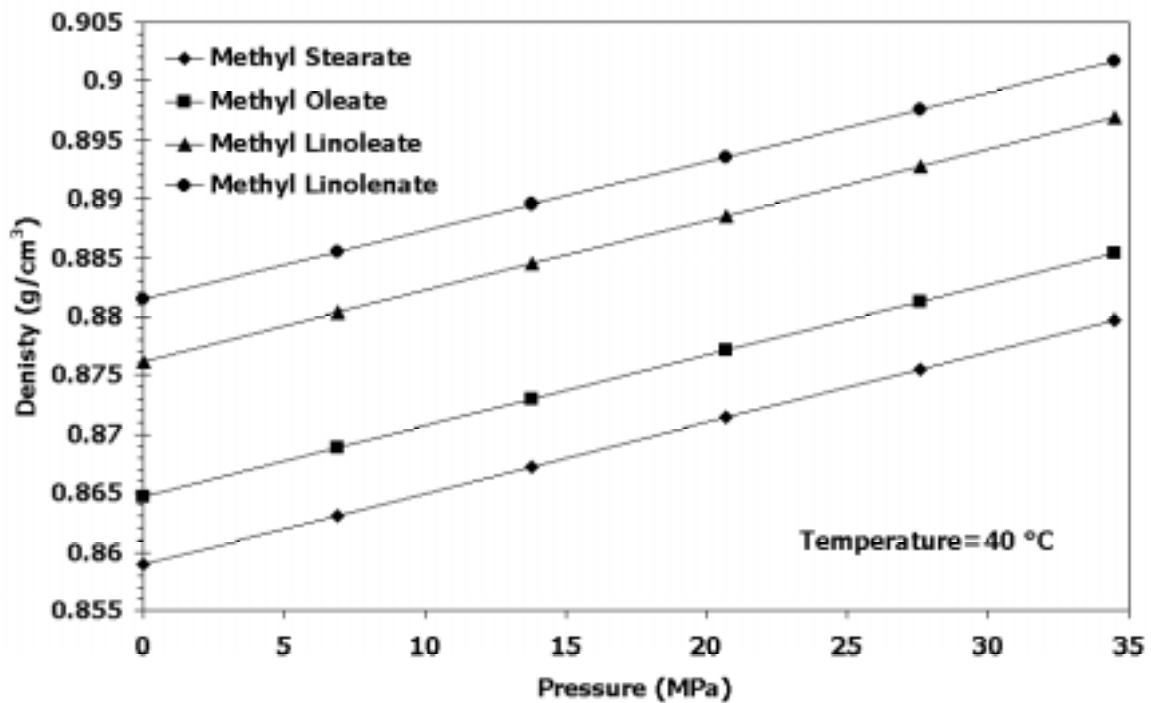

Figure 9. Saturation effect on density at elevated pressures and 40 °C temperature.

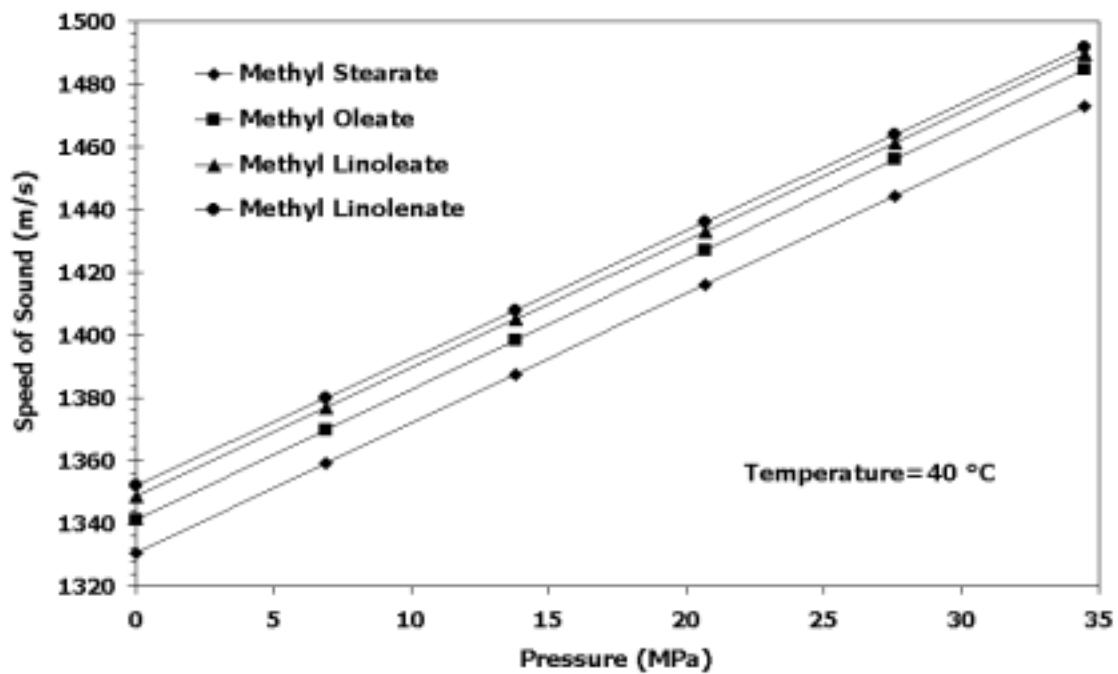

Figure 10. Saturation effect on speed of sound at elevated pressures and 40 °C temperature.

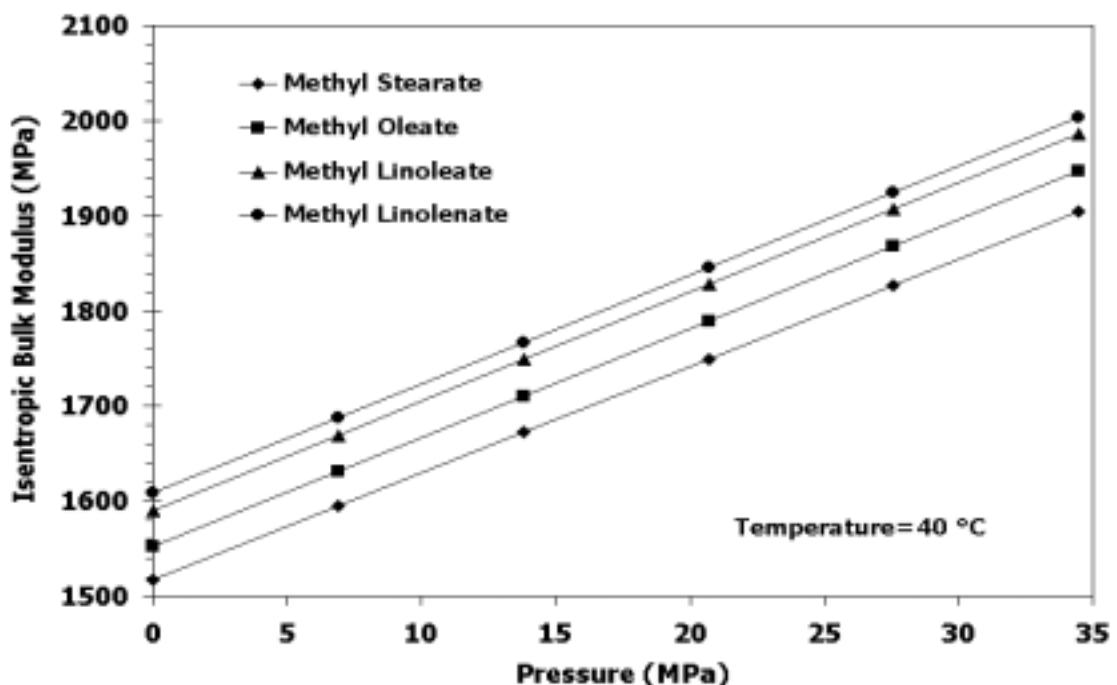

Figure 11. Saturation effect on isentropic bulk modulus at elevated pressures and 40 °C temperature.

The property data for methyl laurate, methyl palmitate, and methyl stearate are provided in Figures 12-14 to show the effect of fatty acid chain length. These data demonstrate that the density, speed of sound, and isentropic bulk modulus increase as the chain length increases which confirms the conclusions drawn for hydrocarbons in reference [7].

Methyl soy ester, ethyl soy ester, and emissions certification grade No.2 diesel fuel (Cert D2) are compared with each other in Figures 15-17. It can be seen that the methyl soy ester is approximately 0.5% more dense than ethyl soy ester and 5% more dense than the certification D2. The speed of sound in the methyl soy ester is about 0.7% and 2.8% faster than that of ethyl soy ester and Certified D2, respectively. The isentropic bulk modulus of the methyl soy ester was 1% higher than that of the ethyl soy ester and 10% higher than the Certified D2.

Figures 18-20 show a comparison of oxidized soy methyl ester and unoxidized soy methyl ester. The sample of oxidized soy methyl ester was provided by the Colorado School of Mines. The extent of oxidation and the method used to oxidize the fuel were not known. Oxidation increased the density slightly but did not increase the speed of sound significantly. As a result of the density increase, the isentropic bulk modulus of the oxidized soy ester is slightly higher than for the methyl isentropic bulk modulus soy ester.

Hydrogenated soy ester and methyl soy ester were compared to see the effect of hydrogenation on the properties. These results are presented in Figures 21-23. Hydrogenation lowers the values of all the three properties as was expected based on the effects of varying saturation observed in Figures 6-11.

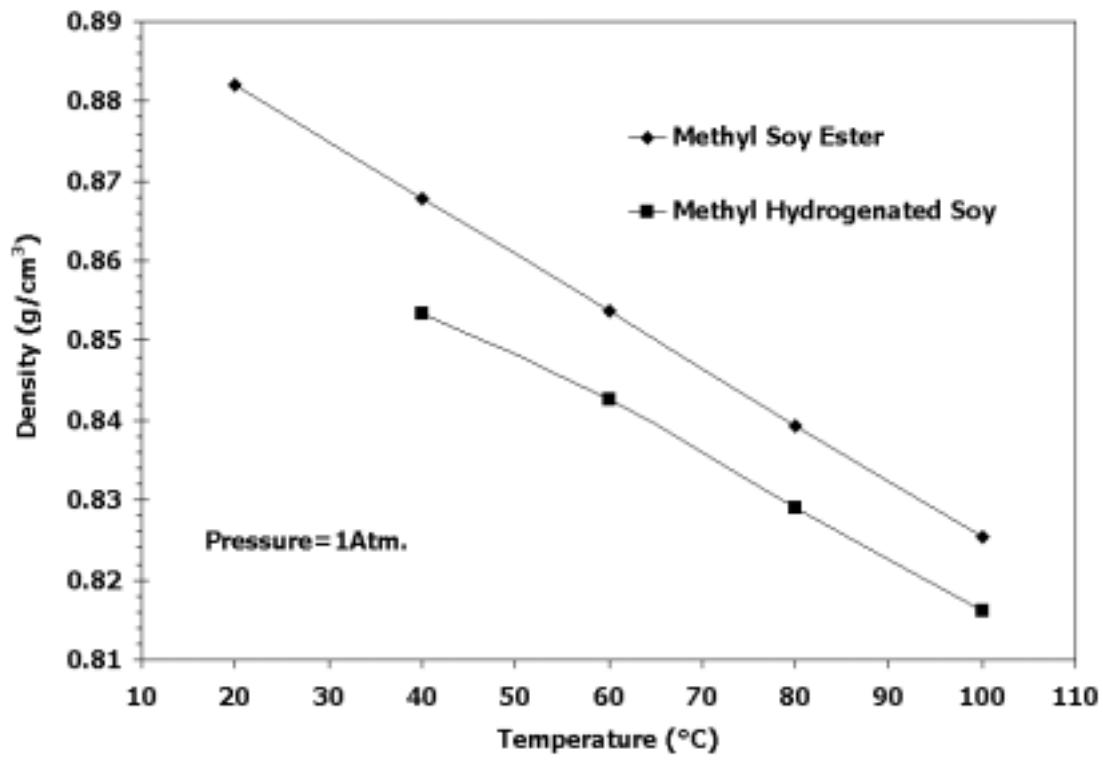

Figure 21. Hydrogenation effect on density of methyl ester.

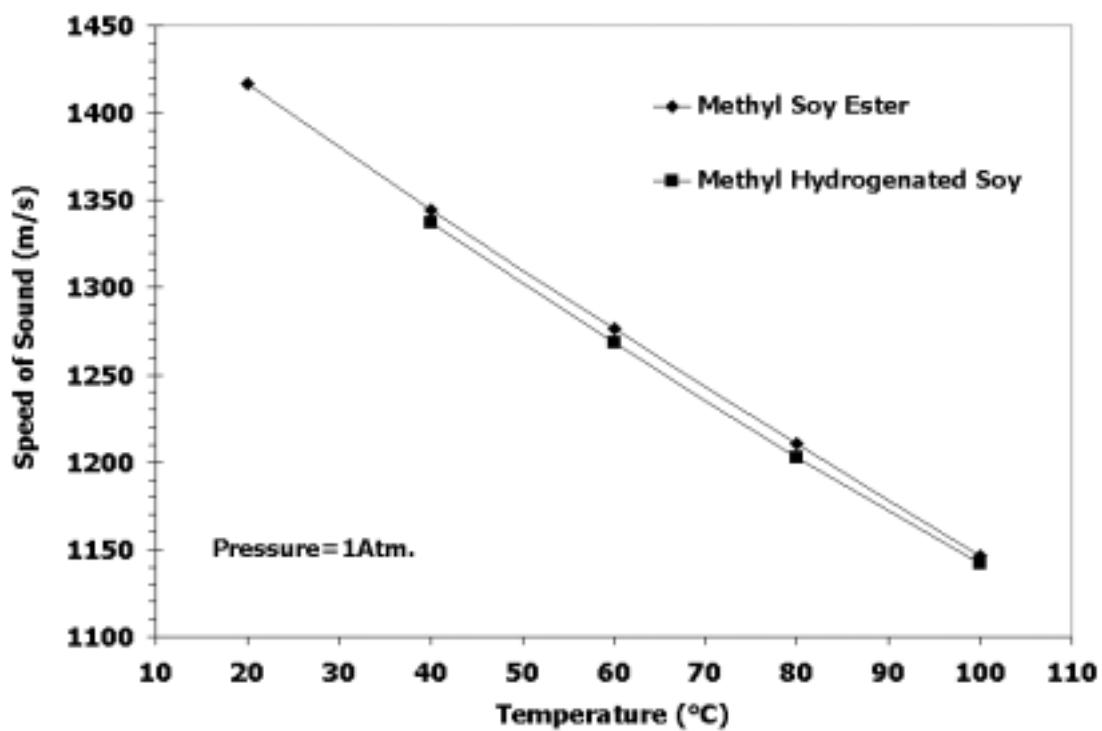

Figure 22. Hydrogenation effect on speed of sound of methyl ester.

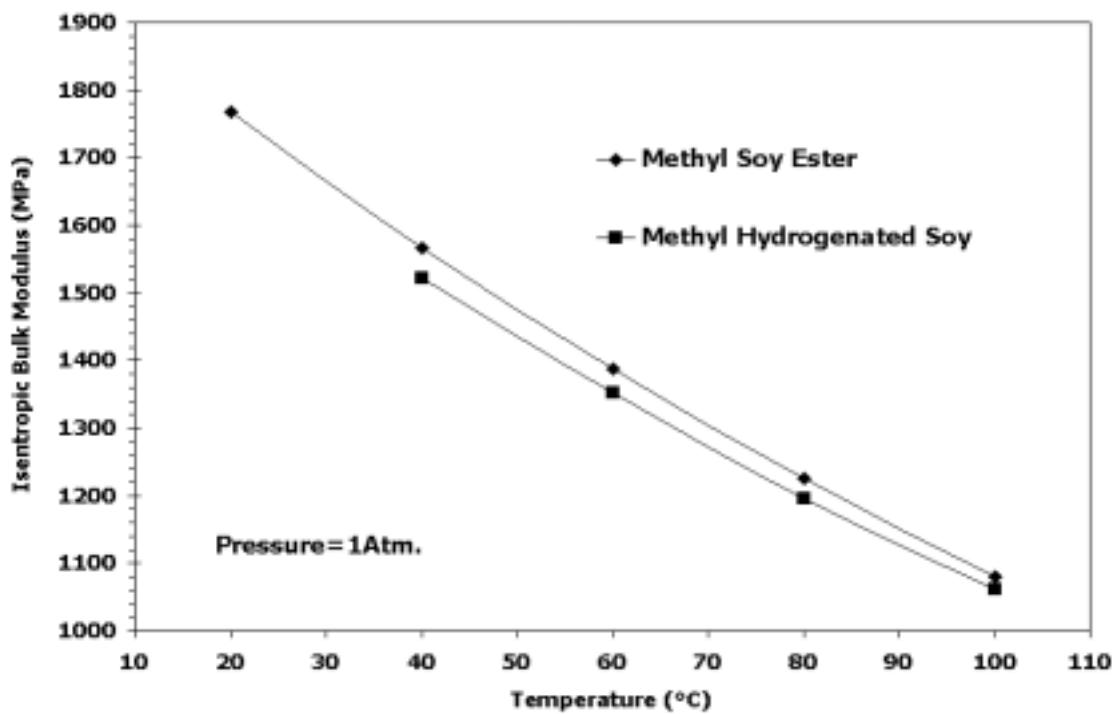

Figure 23. Hydrogenation effect on the isentropic bulk modulus of methyl ester.

The density of the hydrogenated soy ester was 2% lower than that of methyl soy ester, the speed of sound was 0.7% lower, and the isentropic bulk modulus was 2.5% lower than that of methyl soy ester at 40°C.

#### **4. Review of Current Diesel Fuel Injection Equipment**

The purpose of the diesel fuel injection system is to introduce the proper amount of fuel into the cylinder with sufficient kinetic energy to encourage good mixing between the fuel and air. The timing of this process is particularly important because early injection timing produces the high in-cylinder temperatures that cause NOx formation. Engine manufacturers are currently striving to control timing to within 0.1° of crankshaft rotation to minimize engine-to-engine variation in emissions. This section reviews the common equipment used for diesel fuel injection and is followed by sections which estimate the impact of fuel property changes on the injection timing.

There are three basic types of diesel fuel injection systems in common use: pump-line-nozzle systems, unit injector systems, and common rail systems. Only the first two are in common use in the United States. Figure 24 shows a typical pump-line-nozzle (PLN) system. The pump, in this case an inline style pump, supplies pulses of pressurized fuel to the fuel injectors through heavy-walled tubing. Figure 25 shows a section view of the inline pump that displays the individual pumping elements. Figure 26 shows an enlarged view of the pumping element from an inline pump.

The eight major components are:

1. Fuel Tank
2. Primary Fuel Filter
3. Fuel Supply Pump
4. Secondary Filter
5. Injection Pump
6. High Pressure Fuel Lines
7. Injection Nozzles
8. Governor

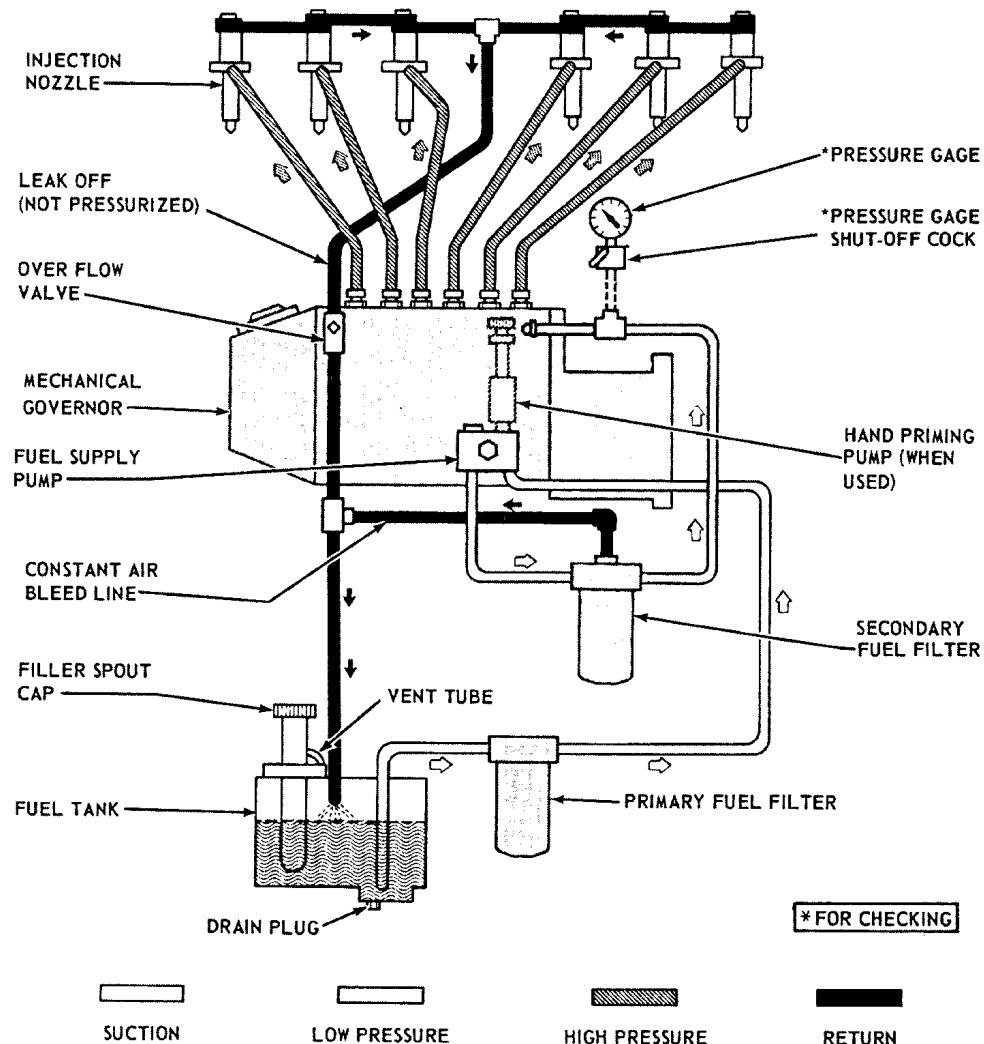

Figure 24. Pump-line-nozzle injection system.

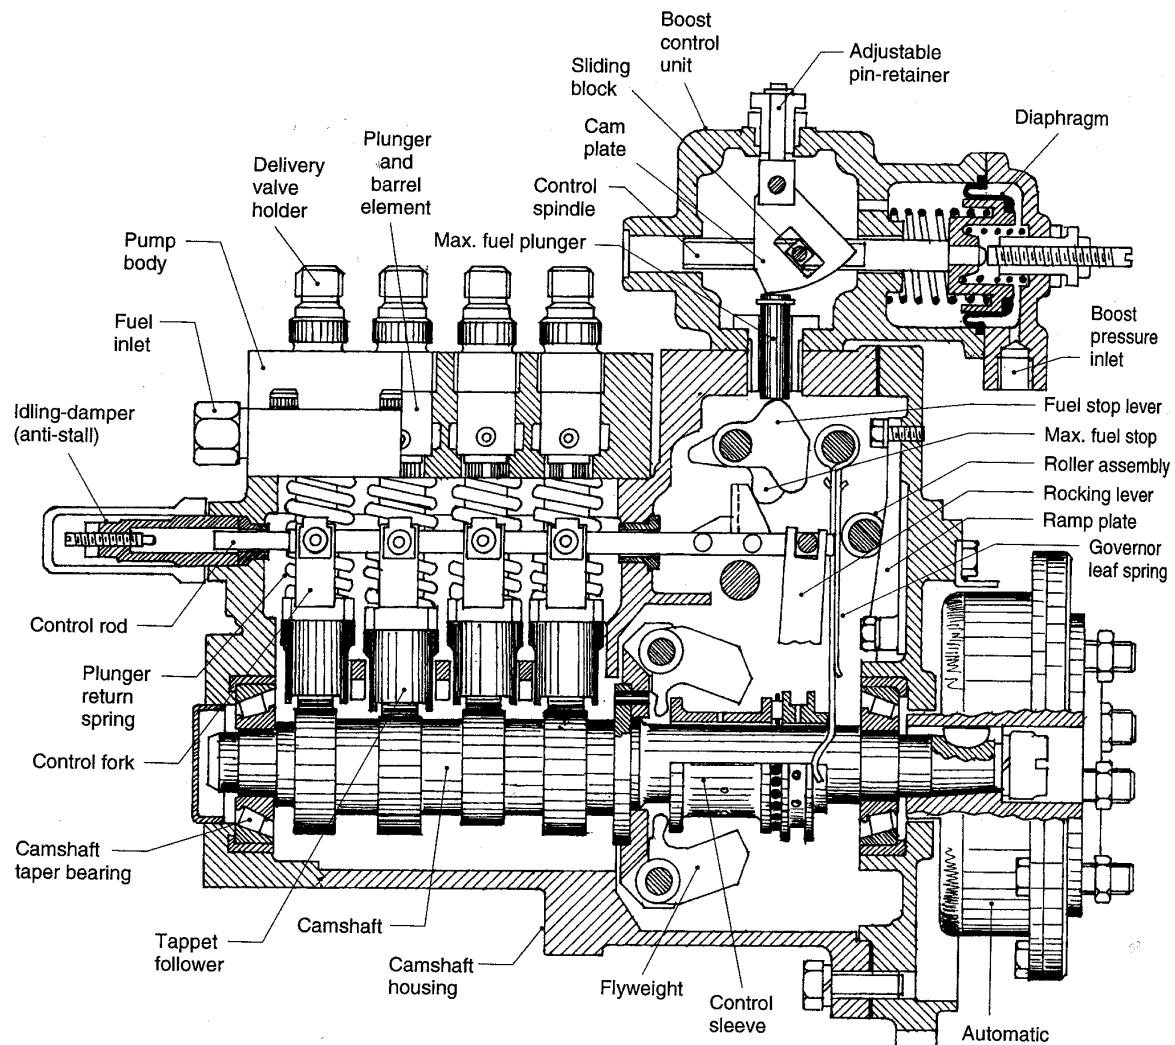

Figure 25. Section View of In-Line Fuel Injection Pump.

From: Heisler, H., *Advanced Engine Technology*, Society of Automotive Engineers, Warrendale, PA, 1995.

The pumping element initiates an injection event when the pump cam pushes the plunger up. When the plunger reaches the point where the feed port is covered by the plunger, the pressure of the fluid starts to rise. The pressure will continue to rise until it reaches the nozzle opening pressure and injection begins. Injection continues until the spill port of the plunger is uncovered which drops the pressure and halts the injection.

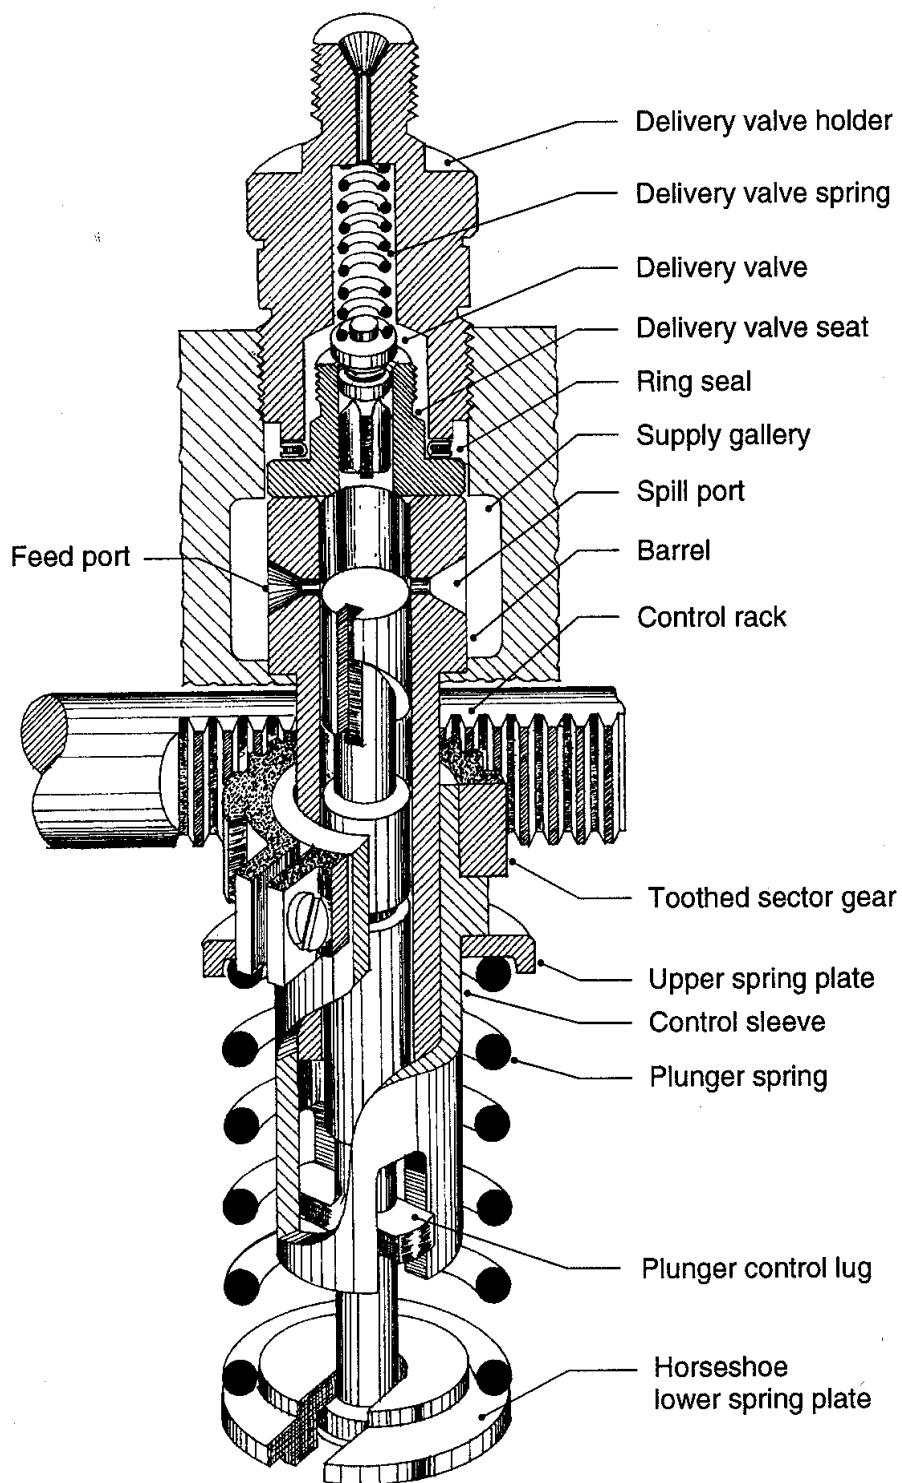

Figure 26. Pumping Element from In-Line Pump.

From: Heisler, H., *Advanced Engine Technology*, Society of Automotive Engineers, Warrendale, PA, 1995.

Figure 27 shows a section view of a typical fuel injector for a PLN system. The injector contains a long drilled passage from the fuel inlet at the top to the needle valve at the bottom. The fuel pressure pushes on the underside of the needle and when it reaches a value that can overcome the spring force (the Nozzle Opening Pressure), the needle lifts and injection starts.

The two fluid properties that will most affect this injection process are the speed of sound and the isentropic bulk modulus. The speed of sound is important because it affects the time required for the pressure rise at the injection pump to travel along the line to the injector nozzle. The isentropic bulk modulus is important because it affects the amount of pressure rise that will result from a sudden change in the volume of the fluid.

The key system variables that will affect the injection timing are the rate of volume change, the volume of pressurized fluid, the nozzle opening pressure, and the length of the fuel injection line. The PLN system has a long fuel injection line which maximizes the impact of changes in the speed of sound. It also has a considerable volume of pressurized fluid, including the volume above the plunger in the pump, the volume of fluid in the injection line, and in the injector itself. The impact of changing to a fuel with a higher speed of sound and less compressible bulk modulus, such as biodiesel, will be to have a faster pressure rise and earlier injection timing.

Figure 28 shows a variation of the high pressure pump used in the PLN system. This style of pump is known as a distributor pump and is most widely used on lower priced and lower power engines.

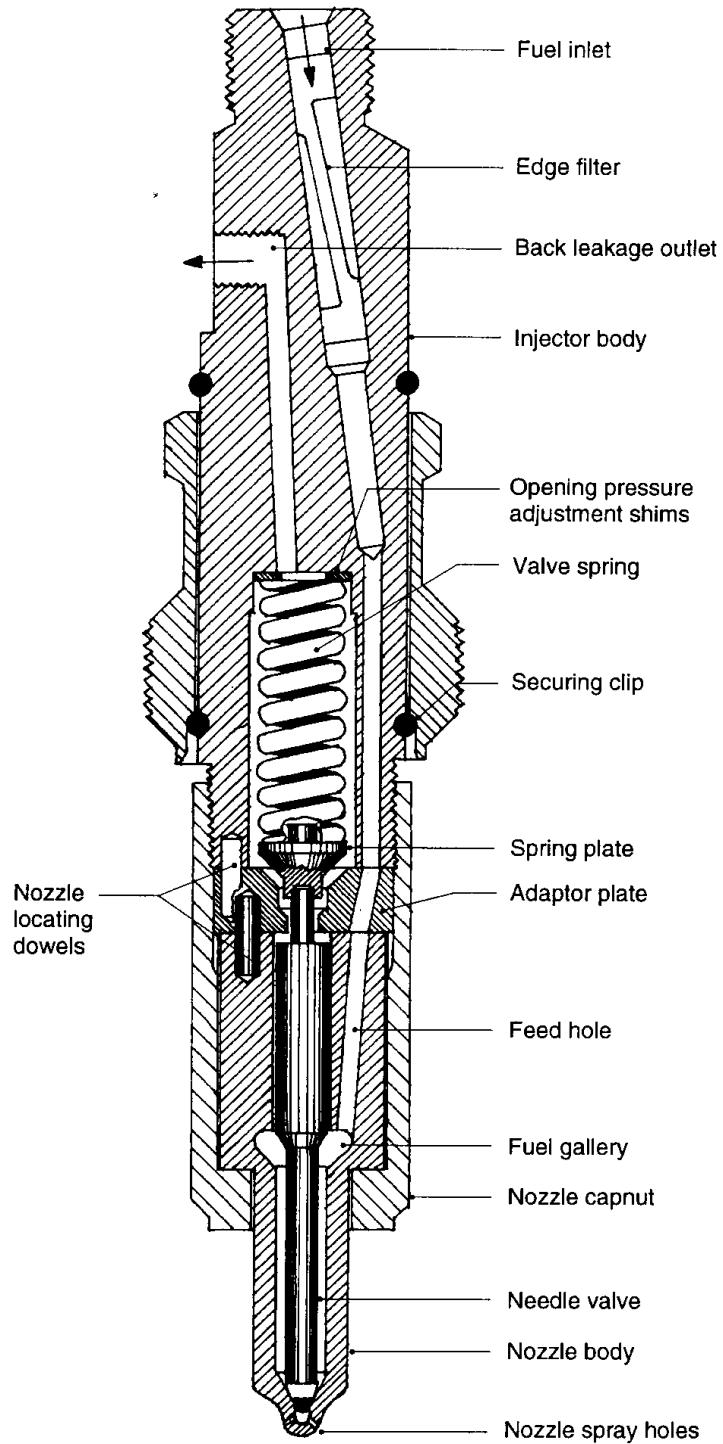

Figure 27. Section View of Fuel Injector.

Ref: Heisler, H. *Advanced Engine Technology*, Society of Automotive Engineers, Warrendale, PA, 1995.

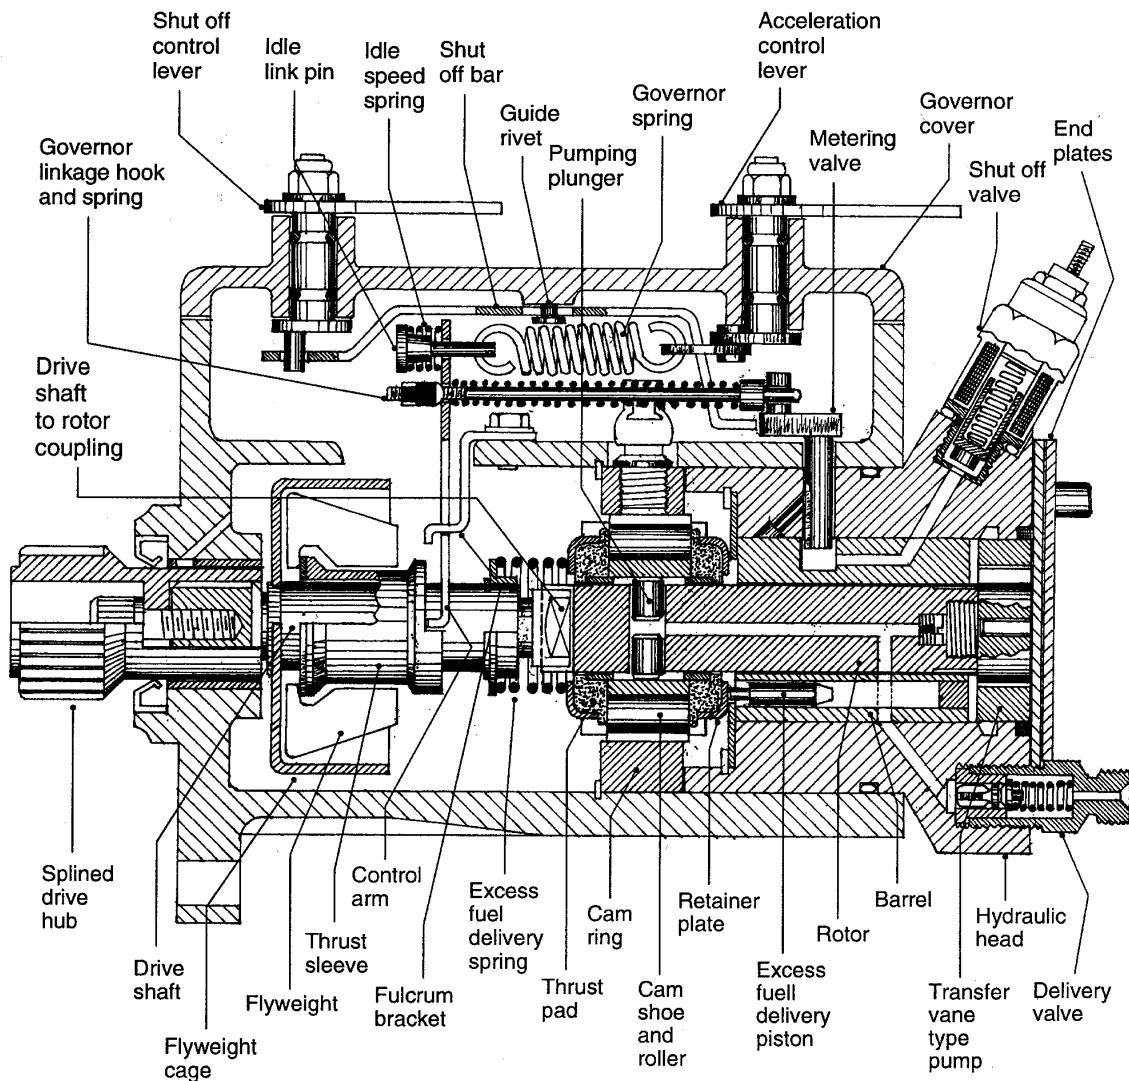

Figure 28. Section View of Distributor-Type Fuel Injection Pump.

Ref: Heisler, H. *Advanced Engine Technology*, Society of Automotive Engineers, Warrendale, PA, 1995.

Figure 29 shows the pumping elements for this style of pump. Distributor pumps use only a single pumping element for the entire engine. The compressed volume for this style of pump will be slightly greater than for the in-line pump due to the distributor section.

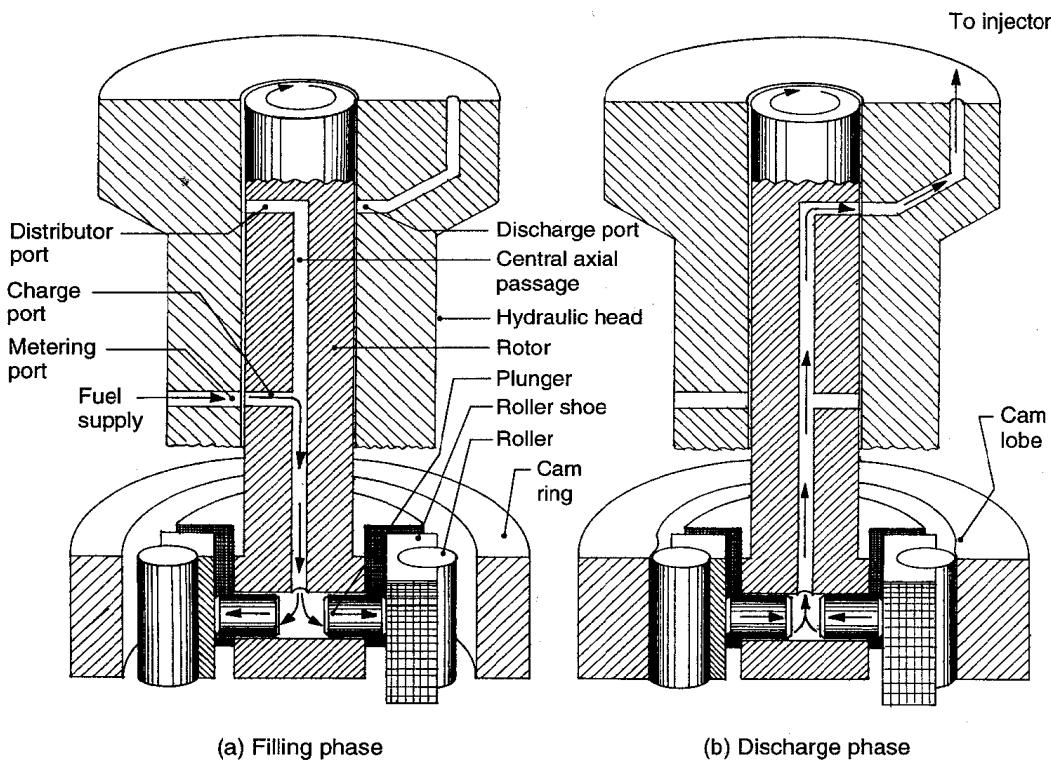

Figure 29. Pumping and Distribution Element of Distributor Pump.

From: Heisler, H., *Advanced Engine Technology*, Society of Automotive Engineers, Warrendale, PA, 1995.

Figure 30 shows a section view of a mechanical unit injector. This style of injector does not use external high pressure lines. The pumping element has been integrated into the injector. The plunger is very close to the nozzle so it would be expected to be much less sensitive to the speed of sound than a PLN system. However, these injectors still have a considerable amount of compressed fuel volume so they will be sensitive to the isentropic bulk modulus.

Figure 31 shows another style of mechanical unit injector used on older Cummins engines. This type of injector has a minimum amount of compressed fuel volume (essentially equal to the fuel injected) and would have the least sensitivity to changes in fuel compressibility and almost no sensitivity to the speed of sound apart from this property's effect on compressibility.

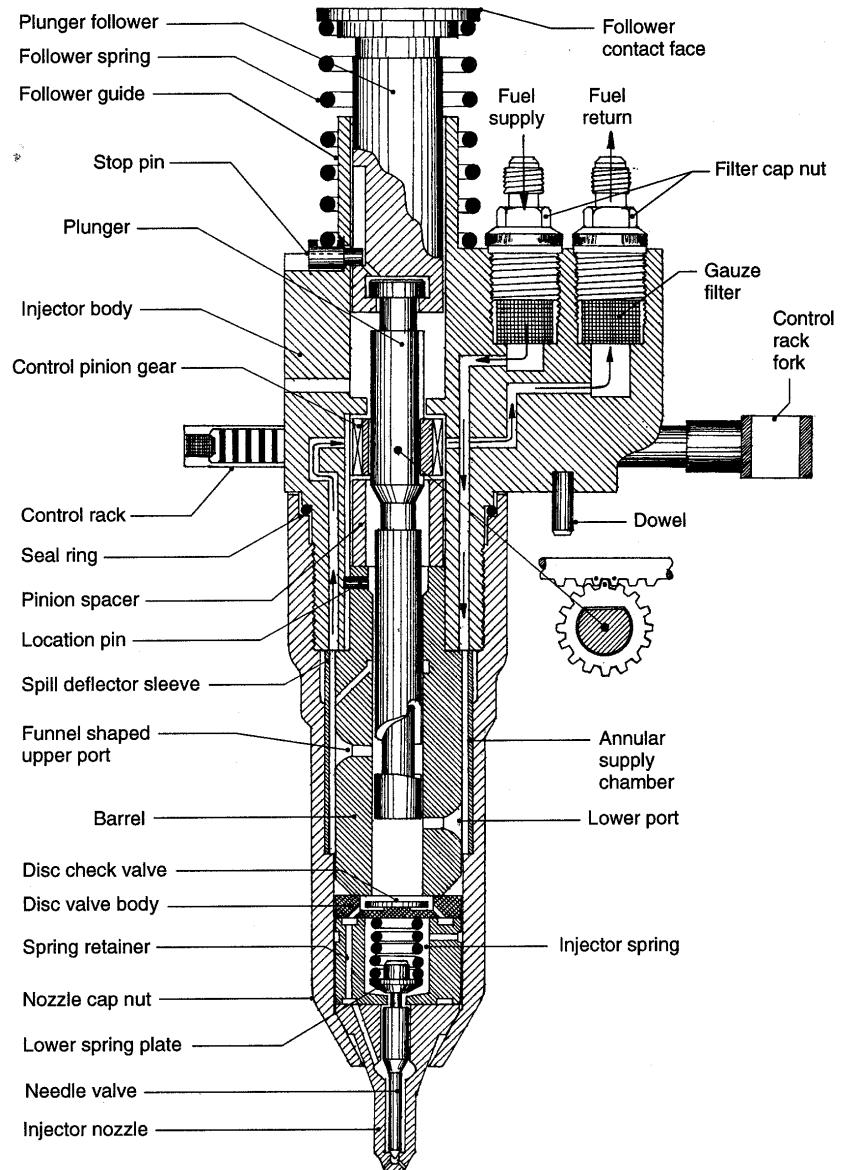

Figure 30. DDC Mechanical Unit Injector.

Ref: Heisler, H. *Advanced Engine Technology*, Society of Automotive Engineers, Warrendale, PA, 1995.

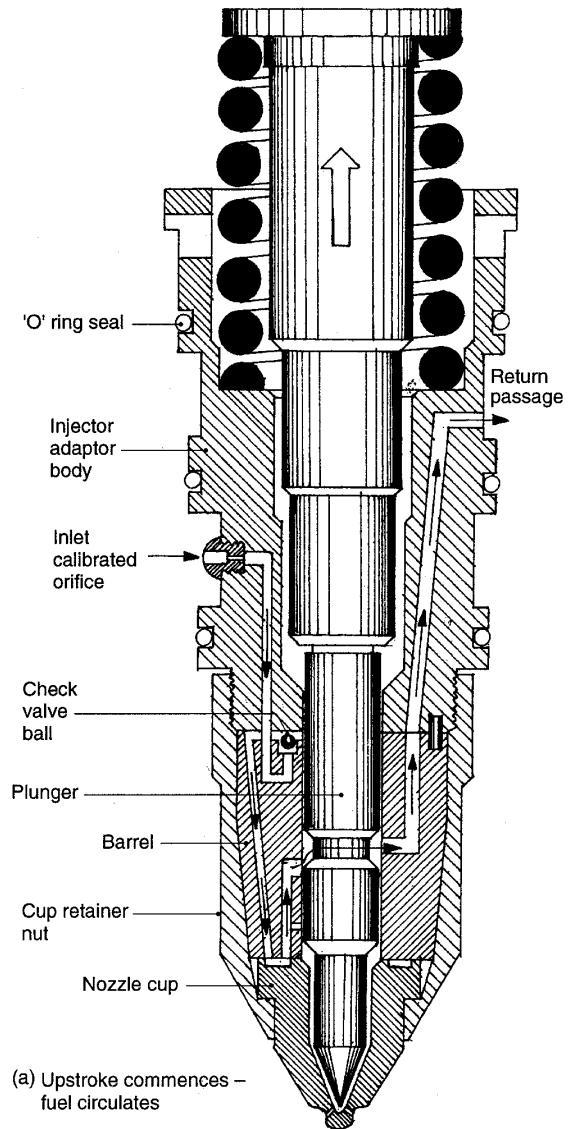

Figure 31. Cummins PT Mechanical Unit Injector

Ref: Heisler, H. *Advanced Engine Technology*, Society of Automotive Engineers, Warrendale, PA, 1995.

Figure 32 shows a state-of-the-art electronic unit injector. This injector is typical of the injectors currently used on most on-highway trucks. Because of the addition of the solenoid, the compressed fuel volume is larger than the mechanical injector and would thus be more sensitive to fuel compressibility. These injectors still do not use external high pressure lines so they would have minimal sensitivity to changes in the speed of sound.

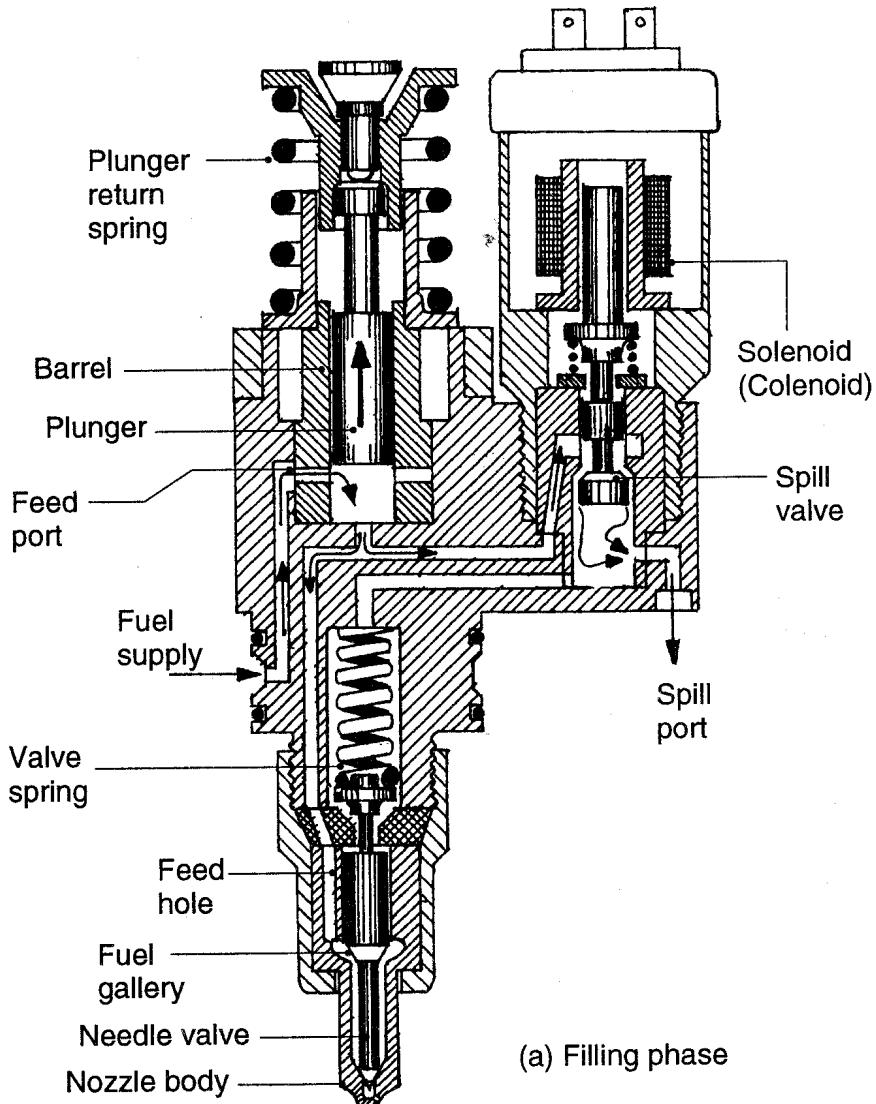

Figure 32. Lucas Electronic Unit Injector.

Ref: Heisler, H. *Advanced Engine Technology*, Society of Automotive Engineers, Warrendale, PA, 1995.

## **5. The Effect of Fuel Viscosity**

All of the injection systems described here have some sensitivity to fuel viscosity and the viscosity of biodiesel is greater than for No. 2 diesel fuel. The most direct impact of a viscosity increase is to decrease the amount of fuel leakage that occurs past the plungers that develop the pressure in the injection system. This reduced leakage will allow the pressure to develop faster and could contribute to earlier injection timing. The effect of viscosity on timing is not currently known

but it should add to the effect of the speed of sound and the bulk modulus. Future work is planned in this area.

## **6. Estimation of the Impact of Fuel Properties on Injection Timing**

It is difficult to estimate the exact impact of the changes in fuel properties on the injection timing without a complete simulation of the injection system. Such a simulation was beyond the scope of this study.

The impact of a change in the speed of sound can be estimated for a Pump-Line-Nozzle (PLN) system as follows. The John Deere 4276T engine that was the source for the injection pressure data shown in Figure 1 has injection lines that are 0.76 m long. If the fuel supplied to the engine is at 40°C, the speed of sound for No.2 diesel fuel and soy methyl ester are 1302 m/s and 1345 m/s, respectively (at atmospheric pressure). A pressure wave moving through diesel fuel in the injection line will take 0.584 ms to propagate from the pump to the nozzle. This corresponds to 7.4 degrees of crankshaft rotation at 2100 rpm, the engine's rated speed. With the biodiesel the pressure wave would arrive 0.24 degrees sooner.

The impact of the isentropic bulk modulus can be estimated by a simple model for fuel compression. If the rate of volume change produced by the injection pump or the unit injector plunger is set equal to the rate of fuel compression, an equation can be developed to predict the time to reach the Nozzle Opening Pressure (NOP).

$$V_\theta A_p = \frac{V_f}{B} \times \frac{dP}{d\theta} \quad (2)$$

where

$V_\theta$  = plunger velocity

$A_p$  = plunger area

$V_f$  = volume of compressed fuel

$B$  = isentropic bulk modulus

$P$  = injection pressure

$\theta$  = crank angle

If all the variables in the equation can be assumed constant, the equation can be integrated to give an expression for the pressure as a function of crank angle.

$$P(\theta) = \frac{B V_\theta A_p}{V_f} \theta + P_o \quad (3)$$

where  $P_o$  is the initial system pressure. The crankshaft rotation required to reach the NOP will be:

$$\theta = \frac{(NOP - P_o) V_f}{B V_\theta A_p} \quad (4)$$

For most injectors the value of  $(NOP - P_o)$  will be 20-35 MPa. For a sample case, a mean value of 27.5 MPa can be assumed. The values of  $V_f$ ,  $V_\theta$ , and  $A_p$  depend on the individual injector design.

For a Lucas EUI like that shown in Figure 31, the following values are estimated:

$V_f = 2000 \text{ mm}^3$

$A_p = 64 \text{ mm}^2$  (9 mm plunger)

$V_\theta = 0.15 \text{ mm/degree}$

At 40 °C, the isentropic bulk moduli are 1398.2 MPa and 1566.9 MPa for No. 2 diesel fuel and soy methyl ester, respectively. For this injector, the estimated time to reach the NOP will be 4.10 degrees of crankshaft rotation for No. 2 diesel fuel and 3.65 degrees for soy methyl ester. This corresponds to a 0.45 ° injection timing advance for biodiesel.

A similar calculation can be performed for a PLN injection system. The values of the parameters will be essentially the same except that the compressed fuel volume will be larger due to the line and the external pump. Using values estimated for the John Deere 4276T engine ( $V_f=3100 \text{ mm}^3$ ), the time to reach NOP will be 6.35 degrees for No. 2 diesel and 5.67 degrees for biodiesel for an estimated injection timing advance of 0.68 degrees. Combined with the advance due to the difference in the speed of sound, this gives approximately 1° of timing advance. This is less than the advance noted in Figure 1. The difference may be due to differences between the actual and estimated values of the injection system parameters, or to viscosity effects. However, it is clear that the changes in the speed of sound and bulk modulus should have a significant effect on the injection timing.

## **7. Conclusion**

Data for the density, speed of sound, and isentropic bulk modulus have been collected for 21 esters or ester blends from 20 °C to 100 °C and from atmospheric pressure to 34.5 MPa. The results are presented as correlations at each temperature for the effect of pressure. Simple calculations estimating the impact of fuel property changes on the injection timing indicate a possible injection timing advance of approximately 1 degree.
